Impact of Very High-Speed Broadband on Company Creation and Entrepreneurship: Empirical Evidence∗

Maude Hasbi†

Abstract

I use micro-level panel data on almost 5,000 municipalities in metropolitan France covering 75% of the population over the period 2010-2015 to estimate the impact of very high-speed broadband networks on company creation in France. I use a count modeling approach with time- and municipal-fixed effects to estimate whether the local presence of a very high-speed broadband network has an impact on business location, in terms of establishment creation. I show that municipalities with a very high-speed broadband network tend to be more attractive for companies, with a positive effect on establishment creation within the tertiary sector: in the commerce service and transport sub-sector. In addition, municipalities with a very high-speed broadband network provide a more favorable environment for entrepreneurship.

Key Words: Fibre; Very High-Speed Broadband; Local Economic Growth; Company Creation

JEL Classification: L13, L50, L96

∗I thank Łukasz Grzybowski, Christine Zulehner and Marc Bourreau for their useful comments. I also thank participants at the 43rd EEA conference (New York, 2017), the 6th MaCCI conference (Mannheim, 2017) and the FSR C&M, CMPF and ENTraNCE Scientific Seminar (Florence, 2017).

1 Introduction

Very high-speed broadband networks are seen as a key enabler for socio-economic development. Their roll-out has been made a priority worldwide and is considered as an investment for the future. Over the last few years, many countries, such as the US, Australia, Japan and Mexico have adopted a national broadband plan to ensure the whole coverage of their territory. In the European Union, the Commission has defined in 2013 a Digital Agenda for Europe, with the objective to provide by 2020 every household with access to at least a 30 Mbps connection and half of the households with a subscription at 100 Mbps. Very high-speed broadband includes both fast and ultra-fast broadband with speed above 30 Mbps. In September 2016, the Commission reiterated its vision to turn Europe into a Gigabit Society by 2025.

The contribution of this paper is to analyze whether very high-speed broadband availability has a causal impact on the creation of new businesses of all non-farm market sectors operating locally. I highlight the impact of these networks on entrepreneurship, with a specific focus on the creation of sole proprietorships. I adopt a technology neutral approach by including all technologies delivering very high-speed services: fibre optical network (fibre to the Home; FttH) and upgraded cable (fibre to the Last Amplifier; FttLA).

---

4“Mexican Digital Agenda” 2011.

The Digital Agenda for Europe distinguishes different ranges of broadband speeds: basic broadband (between 256 Kbps and 30 Mbps), fast broadband (above 30 Mbps and up to 100 Mbps) and ultra fast broadband (above 100 Mbps).

6“State of the Union 2016: Towards a Better Europe - A Europe that Protects, Empowers and Defends”.
7since 2013 Orange and other DSL operators have been upgrading their broadband networks to offer VDSL services, which can provide Internet speeds up to 50 Mbps to some consumers. However, the VDSL technology is not included in the study, because the connection speed depends on the copper line length and as such suffer from signal attenuation.
the first paper to estimate the impact of very high-speed broadband networks on company at a granular local level. The results provide policy-makers with better insights on the impact of very high-speed broadband on the local economy.

This study relies on panel data covering 4,933 municipalities located in metropolitan France, representing approximately 75% of the population, over 6 years, from 2010 to 2015. Panel data allow to control for municipal- and time-specific heterogeneity. The three French largest cities, Paris, Lyon and Marseille are excluded from the analysis. These cities are attractive by themselves for companies and households. In addition, only municipalities with at least 2,000 inhabitants are included in the database.

To estimate the impact of very high-speed broadband networks on local economic growth, I use a count modelling framework with fixed effects. I also use matching estimators as robustness checks. These evaluation methods are commonly used to estimate the average effect of a treatment or policy intervention.

I find evidence of the benefits of very high-speed broadband networks for local economic growth. They enhance municipalities attractiveness for new establishments from the tertiary sector, which rely more on ICTs. In addition, municipalities with a very high-speed broadband networks provide a more favourable environment for entrepreneurship, as it has a positive effect on the creation of sole proprietorships. However, I don’t find any significant effect on the creation of new businesses in the industry or in the construction sectors.

The remainder of the paper is organized as follows. Section 2 discusses the relevant literature on the effect of broadband on economic growth and deployment. Section 3 presents the data.

---

8They are the three largest municipalities in terms of population and are the only one decomposed into arrondissements (districts), with their own mayor and municipal council.
Section 4 introduces the econometric framework. Section 5 presents the estimation results and
Section 6 the robustness checks. Finally, Section 7 concludes.

2 Literature Review

There is a substantial literature on the effect of ICT on GDP and more generally on economic
growth at the national and regional level (see Czernich et al. (2014) and Kretschmer (2009) for
literature reviews). It is widely accepted that, at the national level, ICT adoption has a positive
effect on productivity.

There is an extensive range of macro-level studies which bring empirical evidence on the pos-
itive impact of broadband adoption on economic growth (see Bertschek et al. (2013), Greenstein
et al. (2011) and Holt et al. (2009) for comprehensive literature reviews). Gruber et al. (2014)
evaluate the net economic benefits that would derive from the achievement of the objectives of
the 2020 Digital Agenda for Europe. They find that the economic benefits outweigh the costs of
investment. Besides, they show that the economic benefits are only marginally appropriable by
firms, as they mostly spill over to users and to the national economy. This result confirms other
studies which found a positive impact of broadband availability on consumer surplus (see for
example Crandall et al. (2001) and Dutz et al. (2009)). Thus, Gruber et al. (2014) show that
there is a rationale for public subsidies in the roll-out of broadband networks. Other studies for
the US have found a positive relation between broadband availability and employment (Crandall
et al. (2007), Gillett et al. (2006)). However, there is limited empirical evidence of the effect of
broadband availability on economic growth at the local level, especially in rural areas.

Usually, studies realized at the local-level assess the impact of ICT on variables of local
economic growth (see, for example, Kolko (2012)). There are only few papers focusing specifically on the effect of broadband adoption on local economic growth. Czernich (2011 and 2014) for German municipalities and Jayakar et al. (2013) for eight States in the US find no evidence that broadband availability reduces the unemployment rate. On the contrary, Whitacre et al. (2014) find that broadband adoption, availability and download speeds have an impact on economic growth in rural areas. They use a propensity score matching estimator on local-level data for non-metropolitan US counties for the years 2001 to 2010. They highlight a positive impact on unemployment reduction and on median household income. They also show that rural areas with high levels of download speeds tend to attract more creative class workers and to have a lower poverty level.

As far as firms are concerned, the literature focuses on the impact of broadband on productivity. Haller et al. (2015) show that on average more productive firms are more likely to have a DSL broadband connection, but they find no evidence of an impact of broadband adoption on firms’ productivity or on productivity growth. Similarly, Bertschek et al. (2013) find no effect on labour productivity, but they find a positive effect on firms’ innovation activities. Akerman et al. (2015) show that broadband availability and adoption increases the productivity of skilled workers, acting as a skill complement and lowers the productivity of unskilled workers, acting as a substitute for routine tasks.

Only few studies analyse the effect of broadband on the attractiveness of a territory for firms. In her analysis, Mack (2014) evaluates the correlation between broadband speed and the establishment presence in Ohio. She finds a positive impact of broadband speed for agricultural and rural companies. Using local-level data, McCoy et al. (2016) analyse the impact of local
infrastructure and broadband networks on new business creation in Ireland, excluding the Dublin city region. They find that on average areas covered by broadband are more attractive for firms.

This paper is related to the latter stream of literature. However, most of the studies on the impact of broadband on local economic growth focus on the impact of old generation broadband technologies, such as DSL or co-axial cable technologies and ignore the new high-speed broadband technologies. I attempt to fill this gap by assessing the impact of very high-speed broadband technologies, including fiber optical technology (Fiber to the Home) and upgraded cable technology (DOCSIS 3.0 or Fiber to the Last Amplifier or FttLA).\textsuperscript{9} Besides, though realized at the local level, most of the studies are performed at a more aggregated level, which is either the State or the county. I use data on 4,933 municipalities over 6 years, from 2010 to 2015. To the best of my knowledge, this is the first paper, which at such a granular local level, analyzes the impact of very high-speed broadband network on local economic growth. I specifically focus on the effect of very high-speed broadband networks on the number of firms operating locally and on the creation of new businesses.

3 Data

The data used in this analysis come from a wide range of sources covering a period which spans from 2006 to 2015. Descriptive statistics are reported in the Annex.

Data on the number of establishment creations come from INSEE, the French National Institute for Statistics and Economics Studies. They have been collected for each municipality for the years 2008 to 2015. Information on the three main non-farm market sectors: the industrial

\textsuperscript{9}The FttH technology is also called fibre-to-the-premises (FTTP).
sector, the construction sector and the tertiary sector, are available for each year.

The construction sector is essentially an activity of deployment, installation or maintenance on the customer’s work-site. The industrial sector is also involved in network deployments, but to a lower extent than companies from the construction sector. The industrial sector regroups all activities combining factors of production (facilities, supplies, work, knowledge) to produce material goods intended for the market.

The tertiary sector encompasses a vast field of activities, ranging from commerce to administration, via transport, financial and real estate activities, services to business, personal services, education, health and social services. Therefore, data have been collected for three sub-sectors of the tertiary sector: the commerce, transport and services; the provision of services to companies and the provision of services to households.

I also use a panel dataset on fibre deployment in metropolitan France (Corsica excluded) over 4 years, from 2010 to 2014. The data have been extracted from Orange’s Information System, SFR’s website and Free users’ community websites. Orange is the historical fixed-line incumbent. It owns the legacy copper network, which is used to provide DSL broadband services. SFR and Free are alternative operators which do not possess their own copper network. They provide broadband services by leasing access to the incumbent’s local access network via local loop unbundling (LLU).\[10\] All data on fibre deployments provide information at the municipal level, with each municipality identified by a unique geographic code (the INSEE code). I have information on 36,036 French municipalities out of the 36,192 municipalities counted in metropolitan France in 2014. For each municipality, I know whether Orange and/or SFR has

\[10\] Orange, SFR and Free are also the main competitors on the mobile market.
deployed an FttH network.\footnote{The database used in this study is similar to the one used in Bourreau, Grzybowski and Hasbi “Unbundling the Incumbent and Entry into fibre: Evidence from France”. Further details upon the database construction and data collection provided on request.}

Regarding Free, the data have been extracted from an unofficial website updated by Free’s users community.\footnote{See \url{http://francois04.free.fr/} and \url{http://serge.31.free.fr/}.} The data are consistent with information gathered on other websites, as well as with Free’s Annual Reports. For each municipality, I know whether there are active fibre connections from Free.

Data on cable upgrade have been extracted from Numericable’s website for the years 2010 to 2014. Numericable is the French cable-operator.\footnote{Numericable’s cable network covers 30\% of the population, living mostly in urban areas.} For each municipality, I know whether Numericable has upgraded its cable network to provide very high-speed broadband services.

Table\footnote{ARCEP Decision Nr 2009-1106 from the 22nd December 2009.} shows the number of municipalities covered by each of these four main operators between 2010 and 2014. It is worth noting that during our period of study, in 2013, the regulatory framework has been modified leading to an acceleration in fiber optical network deployment. In France public authorities are promoting co-investment between private operators in less densely populated areas.\footnote{Operators deploying a fiber optical network in less densely populated areas have to publish a call for co-investment and co-invest with interested operators. Operators can co-invest in 5\% of lines or a multiple of 5\% of lines (i.e., they can co-invest in 5\%, 10\%, 15\%, etc. of the lines). Ex-post co-investment is also possible, but subject to a risk premium to compensate the commercial risk supported by the first investor.} Co-investment in the last mile of the network from the optical distribution frame is allowed to alleviate the costs of FttH roll-out.\footnote{In 2013, the list of very high-density areas has been modified leading to more possibilities for co-investment.} Finally, socio-demographic data comes from INSEE. Data on the average fiscal income per municipality has been collected from the General Direction of Public Finance’s website (Gou-
4 Econometric Strategy

The choice of a location for a new company to operate is a fundamental decision, key to its success. Companies incur a fixed cost when settling down. The choice of the company is driven by cost factors, such as the tax regime in the locality, the availability of infrastructures, such as transportation infrastructures, broadband infrastructures, but also by the cost and availability of human capital. In addition, companies consider the potential demand in the market for their products or services.

4.1 Empirical Approach

The empirical literature on business location decisions is generally based on two approaches: discrete choice modelling and count modelling. The first discrete choice modelling approach is based on the analysis of business location decision as a function of firm characteristics, including the size and the industry sector, and alternative local characteristics, including population, human capital and infrastructures. The unit of analysis is the company, whereas in the second count modelling approach, the unit of analysis is the territory. In this latter approach, the analysis consists in assessing how location characteristics can influence business location in the form of the count of businesses in each territorial unit. The underlying assumption is that the number of new establishments that settle in a locality over a time period is determined by

---

16 The average fiscal income is measured in the previous year, as people pay taxes on the year before. In other words, the amount of taxes paid for the year 2015 is calculated on the income received in 2014.

17 See Arauzo-Carod (2008) and Arauzo-Carod and Manjon-Antolin (2012) for a thorough discussion. For recent studies, see Alama-Sabater et al. (2011) and Siedschlag et al. (2013).

18 See Jofre-Monseny et al. (2011) and Bhat et al. (2014).
an equilibrium condition between a stochastic supply function representing the willingness of a company to start its business in the territory and a stochastic demand function for new firms in the territory.\footnote{Following Becker and Henderson (2000), the equilibrium condition can be represented by a reduced form stochastic distribution for the count of new businesses.}

Given the type of data available, I implement a count model to address my main question, which is whether very high-speed broadband networks have a causal effect on creation of new establishments.

I follow the econometric literature by using a fixed effects model to eliminate potential endogeneity stemming from time-varying and time-unvarying regressors. The count of new establishments operating in a municipality for each time period are modelled as a function of the local characteristics, with municipal- and time-fixed effects.

Then, I have,

\[ Y_{it+1} = \alpha + \delta \text{superfastbb}_{it} + \beta X_{it-2} + \gamma Z_{it-2} + year_{t} + \eta_i + \phi_t + \epsilon_{it}. \] (1)

Where:

\[ Y_{it+1} = 0,1,2,... \] (2)

Then, I have

\[ Y_{it+1} = 0,1,2,... \] (2)

\[ Y_{it+1} \] is the count (or number) of new establishments operating in municipality \( i \) at time \( t+1 \).

The variable of interest consists in a dummy variable, denoted \( \text{superfastbb}_{it} \), which indicates whether a very high-speed broadband network has been deployed in municipality \( i \) at time \( t \). I adopt a technology neutral approach by including all technologies through which very high-speed broadband networks have been deployed.
broadband services can be delivered: fiber optical network (FttH) and upgraded cable network (FttLA)\textsuperscript{20}

$X_{it-2}$ is a matrix of location characteristics for municipality $i$ at time $t-2$ and $Z_{it-2}$ a matrix of labour market characteristics for municipality $i$ at time $t-2$. $\eta_i$ is a time unvarying fixed effect which control for differences across municipalities that are constant over time. $year_t$ is a dummy variable for each year capturing year specific fixed effects. $\phi_t$ captures regional or departmental specific time trend\textsuperscript{21} Finally, $\epsilon_{it}$ is an i.i.d. standard error clustered at the municipal level, capturing unobserved factors.

\subsection*{4.2 Potential Endogeneity}

As highlighted in the literature, there is a potential endogenous effect of broadband networks on company creation and more generally on economic activity, see, for example, Kolko (2012), Mack et al. (2011) and McCoy et al. (2016)). Economic activities are more likely to thrive in areas with enhanced broadband infrastructures. In the meantime, areas with better broadband infrastructures are more likely to attract economic activities. Therefore, this effect materializes mostly as reverse causality between the number of companies operating locally and very high-speed broadband availability.

In their analysis of the impact of local broadband infrastructures on new business establishment, McCoy and al. (2016) argue that the endogenous relationship that exists between broadband networks and companies is more likely to affect the stock of existing companies rather than the flow of company creations. Operators would rather decide to roll-out a broad-

\textsuperscript{20}Due to data constraints, I estimate the effect of very high-speed broadband networks at time $t$ on the number of new establishments at time $t+1$. The latest data available for establishment creation is 2015. I estimate here a short-term effect. With longer dataset, it could be possible to estimate a medium or long-term effect.

\textsuperscript{21}There are 21 regions and 93 departments.
band network in areas with a large number of companies and companies would rather settle down in areas with improved broadband infrastructures.

To mitigate this endogeneity problem, they restrict their analysis to new firms in each year and control for the pre-existing employment levels for each area and for each time period. Similarly, to lessen this problem of endogenous relationship, I follow their argument and I estimate the impact of very high-speed broadband networks on the number of new establishments created in each year, instead of the total number of establishments operating locally. I also control for pre-existing level of companies for each area and each year using a 2 years lagged variables. Nevertheless, I assume that my estimation results would likely suffer from an upward bias.

In addition, the local labor market variables may also suffer from reverse causality. It includes the proportion of people with a third-level diploma, the number of people from the different socio-professional groups and the unemployment rate. Households could choose to locate in areas with better job prospects and companies in areas in which they could higher their labor forces. To alleviate this concerns, I use 2 years lagged variables. I conduct robustness checks with lags of 3 years and 1 year, which give similar qualitative results.

Omitted variables may also be a potential source of endogeneity. For example, operators may have higher incentive to deploy a very high-speed broadband network in areas in which they can benefit from a more favourable tax regime or in which there is higher demand for faster broadband services. To mitigate this problem, I follow the econometric literature by using time-varying and time-unvarying fixed effects. I also add region/ department specific time trends.
4.3 Empirical Models

In their decision to settle in a locality, I expect firms to be influenced by the potential market size and the quality of demand, in terms of expected purchasing power. In addition, I expect that firms take into account the level of education and the composition of the population, in terms of qualification. I use lag variables of two years to control for potential issues of reverse causality.\textsuperscript{22}

The model is estimated using a sub-dataset, which excludes the three main French agglomerations, Paris, Lyon and Marseille. They are the three largest municipalities in terms of population and are the only one decomposed into arrondissements (districts), with their own mayor and municipal council.\textsuperscript{23} In addition, only municipalities with at least 2,000 inhabitants are included in the database. It is rather unlikely that private operators deploy a very high-speed broadband network in a municipality with less than 2,000 inhabitants. Therefore, the database includes 4,933 municipalities over 6 years, from 2010 to 2015.

\textsuperscript{22}For all specifications different lags have been estimated, results are qualitatively similar.
\textsuperscript{23}Population in 2013: Paris: 2.2 millions inhabitants, Marseille: 855,393 inhabitants, Lyon: 500,715 inhabitants, the fourth largest is Toulouse with 458,298 inhabitants, but even though the municipality size is comparable with Lyon, the density of population is much lower: 3,942 inhabitants per km\textsuperscript{2}, compare to 10,583 inhabitants per km\textsuperscript{2} for Lyon and there is no arrondissement in Toulouse.
For the number of establishment creations\footnote{I use log-transformation for better interpretation. Few municipalities have 0 establishment creation, I set this number to 1. This can be done, because the number of 0 company creation is rather low: 1.4\% for new establishments; 4.8\% for new establishments from the construction sector; 0.7\% for the commerce, service and transportation sub-sector; 1\% for the provision of services to households sub-sector; 5.2\% for the provision of services to companies sub-sector; 0\% for the creation of new companies run by one individual. Only establishment creation in the industry sector display a higher number of 0, with 17\% of the municipalities having 0 establishment creation from the industry sector. However, results are qualitatively similar in terms of signs and significance.}

\[ \ln_{\text{new establishment}}_{i,t+1} = \alpha + \delta \text{ superfastbb}_{i,t} + \beta_1 \text{ establishment}_{i,t-2} + \beta_2 \ln_{\text{households}}_{i,t-2} + \beta_3 \text{ density}_{i,t-2} + \beta_4 \text{ income}_{i,t-2} + \gamma_1 \text{ unempl}_{i,t-2} + \gamma_2 \text{ perc uni diploma}_{i,t-2} + \gamma_3 \text{ employment groups}_{i,t-2} + \text{ year}_t + \eta_i + \phi_t + \epsilon_{it}, \] (3)

where \( \ln_{\text{new establishment}}_{i,t+1} \) represents the number of new companies (in log) that have been created in municipality \( i \) at time \( t + 1 \) and \( \text{establishment}_{i,t-2} \) represents the number of establishments operating in municipality \( i \) at time \( t - 2 \). As a matter of fact, the number of establishment in a locality is highly correlated with the number of establishment in the previous years. I control for firm characteristics by disaggregating the establishment into the three non-farm market sectors of the economy: the construction sector, the industrial sector and the tertiary sector.

The tertiary sector is the one which is predicted to benefit the most from the presence of very high-speed broadband. However, this sector is quite large and includes activities ranging from commerce, transportation, services and administration. It is however possible to disentangle the effects of very high-speed broadband networks on the creation of establishments from three sub-sectors: the commerce, transport and services; the provision of services to companies and the provision of services to households.

I also add the number of households (in log) in municipality \( i \) at time \( t - 2 \), which is a proxy...
for the market size, as well as the population density in municipality $i$ at time $t - 2$. Besides, I add the average fiscal income and the unemployment rate in municipality $i$ at time $t - 2$. Both variables are approximations for the quality of demand, in terms of purchasing power.

As education plays a role on the decision of firms to operate locally, I add the percentage of inhabitants with a diploma from superior education in municipality $i$ at time $t - 2$, as well as, the number of inhabitants of the different socio-professional groups, $employment\_groups_{it-2}$ in municipality $i$ at time $t - 2$, which are a proxy for the qualification of the population. There are 6 socio-professional groups: Farmers (group 1), craft workers, retailers, and business owners (group 2), intermediate occupations (group 3), white collars (group 4), employees (group 5) and blue collars (group 6).

In a second specification, I make a specific focus on entrepreneurship, by assessing the impact of very high-speed broadband networks on the creation of sole proprietorships, i.e. the creation of companies owned and run by one individual:

$$\ln_{new\_proprietorship_{it+1}} = \alpha + \delta superfastbb_{it} + \beta_1 establishment_{it-2}$$

$$+ \beta_2 ln_{households_{it-2}} + \beta_3 density_{it-2} + \beta_4 income_{it-2}$$

$$+ \gamma_1 unempl_{it-2} + \gamma_2 perc\_uni\_diploma_{it-2} + \gamma_3 perc\_no\_diploma_{it-2}$$

$$+ \gamma_4 employment\_groups_{it-2} + year + \eta_i + \phi_t + \epsilon_{it},$$ (4)

where $ln_{new\_proprietorship_{it+1}}$ represents the number of new sole proprietorships (in log) that have been created in municipality $i$ at time $t + 1$. I add in the set of explanatory variables, the percentage of inhabitants with no diploma in municipality $i$ at time $t - 2$. As during a time of unemployment, some people which face difficulties to find a job, may decide to create their
own business. This has been observed with the 2008 economic crisis, with an increase in the
number of sole proprietorships (see descriptive statistics).

Nevertheless, I also estimate all specifications without the number of establishments oper-
ating in municipality $i$ at time $t - 2$ to ensure that this variable does not impact or hide the
significance of others. Results are qualitatively similar in terms of sign and significance, they
also display coefficients of similar amplitudes. The same exercise has been made without the
different socio-professional groups; results are also qualitatively similar.

5 Estimation Results

Tables 5 to 8 show the estimation results of the impact of very high-speed broadband on es-
tablishments creation and on new proprietorships. In the first specification (1) there is no
geographic specific time trend, in (2) specific time trends at the regional level are added, in (3)
specific time trends at the department level are added.

I find that the deployment of very high-speed broadband networks favours local economic
development by increasing the number of new establishment created locally. Table 5 shows that
the number of new establishments increases by an average of 2.8% with the presence of a very
high-speed broadband network. This effect is reduce to 1.6% when adding region specific time
trends and becomes insignificant with department specific time trends.

To better capture the effect of very high-speed broadband on the local economy, the estab-
ishments are disaggregated into the three main categories of the non-farm market sector: the
industrial sector, the construction or building sector and the tertiary sector.

\footnote{Results are available upon request.}
As expected, municipalities benefit from the spill over of the local presence of very high-speed broadband networks, helping them to maintain and develop a healthy economic sector. However, the presence of very high-speed broadband networks does not have an impact on the creation of all types of establishments of the non-farm market sector. I find a positive and significant impact only for the creation of establishments from the commerce service and transportation sector, in which firms rely more on ICT to conduct their business. In this sub-sector, the number of new establishments increases by 6%. This effect is reduced to a bit less than 4% with the introduction of region or department specific time trends.

Not surprisingly, I don’t find any significant effect on the creation of establishments of any of the other two tertiary sub-sectors, i.e. the provision of services to companies and to households. Besides, very high-speed broadband networks do not have any significant impact on establishment creation in the industry sector and in the construction sector.

I also highlight the existence of a positive impact of very high-speed broadband networks on the creation of sole proprietorships, with an increase in new companies created by one individual by roughly 1.8%. This effect is of somewhat similar amplitude with the introduction of region or department specific time trends (1.7% and 1.5% respectively).

Therefore we highlights the importance of adding geographic specific time trend to take into account the existence of specific policies impacting geographic areas differently. Impacts of very high-speed broadband networks are lowered. Besides, in the third specification with specific time trends at the department level, the effect of very-high speed broadband network on the number of newly created establishment is no longer significant.

Estimation results tend to confirm the findings of McCoy et al. (2016), which highlight that
on average areas covered by broadband are more attractive for firms. Besides, the estimation results are also in line with the empirical literature, especially the study from Gruber (2014), which shows that economic benefits from the achievement of the 2020 Digital Agenda for Europe mostly spill over to users and to the national economy.

6 Robustness Checks

In order to test the robustness of the results, estimations are conducting using the nearest neighbour (difference-in-differences) matching estimator method. Table 9 shows covariate balance statistics and assesses the balance between treatment groups in the means and in the variances. Estimation results are provided in Tables 10 and 11. Figures 1 to 3 show the parallel trends assumption between the treated and the control group for establishment creation for different sectors of the economy. Table 12 provides an overview of the estimation results for all models.

6.1 Assumptions and Settings

Matching techniques are non-parametric estimators used to estimate average treatment effect (ATE). ATE are commonly used to measure the average impact of a treatment or a program intervention, by measuring the difference in outcome between a treated group and a control group (Rosenbaum and Rubin (1983)).

\[ Y_{it+1}(1), (Y_{it+1}(0)) \] denotes an outcome which is realized at time \( t + 1 \) if municipality \( i \) receives (doesn’t receive) at time \( t \) a treatment \( d_{it} = 1 \) (\( d_{it} = 0 \)).

The outcome of interest could either be the number of new establishments created locally or the number of new sole proprietorships. The treatment variable consists in a dummy variable
indicating whether a treatment has been applied, i.e. whether a very high-speed broadband network is deployed in municipality \(i\) at time \(t\). The control group consists in otherwise similar municipalities in terms of observable characteristics.

Then, the average treatment effect on the treated (ATT), which represents the average gain from the treatment for those who actually were treated, writes as follows

\[
ATT = E(\Delta Y_{it+1}(1) \mid d_{it} = 1) - E(\Delta Y_{it+1}(0) \mid d_{it} = 1). \tag{5}
\]

The first term represents the expected value of the outcome of interest, at time \(t + 1\), in municipalities in which a treatment has been received at time \(t\), which is observable. However, the second term in Eq.(6) is non-observable. It represents the expected value of the outcome of interest, at time \(t + 1\), for the control group, had a treatment been received at time \(t\). When evaluating the impact of a policy, or here of an investment decision, the researcher faces an identification issue. Besides, the treatment distribution may suffer from a selection bias. Considering the high costs of deployment, operators will select the municipalities in which to invest first depending on their return prospects. To alleviate these issues, matching estimators seek to reproduce the treatment group among the non-treated group using observable characteristics. Then, the key parameter is to identify the relevant set of matches.

The set of relevant matches is:

\[
\text{ln}_{\text{households}}_{it-2}, \text{density}_{it-2}, \text{income}_{it-2}, \text{unempl}_{it-2}, \text{perc}_{\text{estab}_{commserv}}_{it}, \text{year}. \tag{6}
\]

The key variables for the matching are the number of households (in log), the population
density, the average fiscal income and the unemployment rate, all in municipality $i$ at time $t - 2$. In addition, to match municipalities with the same type of economy, I introduce the percentage of companies from the commerce and service sector in municipality $i$ at time $t$.

Table 9 provides a table of distributional test statistics for the means, variances and skewness of key variables included in the matching process. By comparing the distribution of the different variables between the treated and control group, I ensure that the two groups are similar in terms of observable characteristics. Besides, I assess the balance between the treatment groups in the means, by using the standardized difference, and in the variances, by using the variance ratio. Table 9 shows that the control group created through the matching is similar to the treated group, in terms of households number, population density, income and unemployment rate. The percentage of inhabitants with no diploma is slightly higher in the control group, while the percentage of inhabitants with a diploma from the superior is slightly higher in the treated group.

As in the difference-in-differences method, one of the key assumption is that the treated and the control groups follow a parallel trend in the pre-treatment period. Absent treatment, both groups would have evolved the same way. Therefore, the difference in the outcome variable in the post-treatment period is assumed to be due to the treatment effect. Figures 1 to 3 show the parallel trends assumption for the number of new establishments, the number of new establishments from the commerce service and transport sector, as well as for the number of new sole proprietorships. We also observe from Figure 3 a small change in trends for the number of new sole proprietorships in the year following the treatment.

Considering that the average effects are estimated on the treated population and not on the
whole population, it is expected to find higher effects than with the previous model.

6.2 Estimations Results

Table 10 confirms the results obtained with the panel data model. I find that the number of new establishments increases by an average of 5% with the presence of a very high-speed broadband network. Unlike in the previous estimation, I find a positive average impact on the creation of establishments in the industry sector, which increases by 9%. However, the impact of very high-speed broadband networks on the number of new establishments from the construction sector is still not significant.

Similarly, I find that municipalities in which a very high-speed broadband network has been deployed are more attractive for establishments from the commerce service and transport sector. The creation of new establishments in this sub-sector increases by an average of 4.6%. Besides, unlike in the previous estimation, I find a positive effect of very high-speed broadband networks on the creation of establishments providing services to companies. Their number increases by an average of 5%.

Table 11 also confirms results from the panel data estimation as regard the creation of sole proprietorships. Municipalities in which a very high-speed broadband network has been deployed seem to favor entrepreneurship, with an average increase in the number of new sole proprietorships of 3.6%.

Table 12 provides a summary of the effects of very high-speed broadband networks on local economic growth for each model and specification. As expected, coefficients are slightly higher for the matching estimator model compared to the main model, as the average effect is estimated
on the treated group. There are still two main differences between the models. Unlike the main panel data model, the ATT model shows a positive effect of the presence of a very high-speed broadband network on establishment creation from the industry sector. In addition, the ATT model highlights the existence of a positive effect on the creation of establishment providing services to companies. As mentioned above, the ATT model is estimated on the treated population and can therefore display higher coefficients and also highlights impacts which prevail in the treated population.

7 Conclusion

Very high-speed broadband networks are considered by policy makers to be a significant factor of economic growth in many sectors of the economy. There is a large consensus among economists to support the benefits of infrastructure investment for the national economy. Many countries worldwide have adopted a national broadband plan, in which they set ambitious objectives for broadband availability.

A technology neutral approach is adopted to estimate whether very high-speed broadband networks, either fibre optical network (fibre to the Home; FttH) and upgraded cable have an impact on the creation of new local businesses of all non-farm market sectors and on the creation of sole proprietorships.

This study relies on micro-level panel data covering almost 5,000 municipalities located in metropolitan France, representing approximately 75% of the population, over 6 years, from 2010 to 2015. The three French largest cities, Paris, Lyon and Marseille are excluded from the analysis. Only municipalities with at least 2,000 inhabitants are included in the analysis.
As infrastructure investment produces spillovers, it affects all sectors of the national economy. However, the economic benefits vary significantly across sectors. The estimation results confirm that the presence of very high-speed broadband networks enhances municipality attractiveness for the creation of new businesses. As foreseen by policy makers and economic analysts, very high-speed broadband networks have on average a positive impact on the creation of establishments operating in the commerce, service and transport sector, where indirect jobs requiring ICT skills are mostly found. However, I don’t find any significant effect on establishment creation in the construction and industry sectors.

I observe a positive effect on the creation of sole proprietorships. Municipalities in which a very high-speed broadband network has been deployed seem to provide a favourable environment for the creation of companies owned by one individual.

A limitation of this paper, though, is that the causal relation I intend to estimate between the presence of very high-speed broadband networks and the number of establishments operating locally and more generally economic activity may be subject to endogeneity. I try to mitigate this problem by using the number of establishment creation instead of the total number of establishments operating locally. Besides, I use lagged variables and geographic specific time trends to control for this effect. Therefore, the estimation results may suffer from an upward bias with coefficients being overestimated. Another way to take into account reverse causality in this paper consists in relying upon modelling designed specifically for policy evaluation, such as the matching estimator method.

Another limitation of the paper is that the deployment of very high-speed network is fairly new. As a result, it is only possible, at this stage, to estimate the short-term effects of their
presence on local economic growth. However, it fills a gap in the literature by providing empirical
evidence on the impact on next generation broadband technologies on company creation at the
local level.

Thus, this paper highlights the benefits of very high-speed broadband networks on local
economic growth, providing further grounds for policy makers to stimulate investments from
private operators. Local government may also consider subsidizing or deploying their own very
high-speed broadband networks to bring their benefits in areas where private investment is unlikely
to occur. By financially supporting the deployment of broadband networks in areas which are
not attractive for private operators, local government may help to open up small or medium
municipalities, contributing to their economic development and to the reduction of the digital
divide.

</table>

Robust standard errors in parentheses: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$
Figures 1 to 3 show that for all these variables, the parallel trend assumption is respected in the pre-treatment period. I also highlight a small change in the number of establishment creation after 2013, which increases slightly in the treated group, compared to the control group in which the number of establishment creation seems to be stable.

Figure 2 shows the same change in trends after 2013 for the number of new establishments from the commerce, service and transport sector created in treated municipalities.
Figure 2: Parallel lines assumption: number of new establishments from the commerce service and transport sector

Figure 3: Parallel lines assumption: number of new sole proprietorships
